# Air Quality Data Accuracy Report

Madison Ave, 11011  
Lat, Long : 40.79, -73.94

● **200 AQI** | Unhealthy

PM 2.5      186  $\mu\text{g}/\text{m}^3$

PM 10      158  $\mu\text{g}/\text{m}^3$

**01****Introduction****02****Accuracy of Ambee's real-time  
Air Quality data v/s station v/s  
Breezometer****03****Accuracy of Ambee's 48-hour Air  
Quality forecast data v/s on-  
ground station data**

# Ambee's air quality dataset

Comprehensive pollution parameters to drive business impact

Parameters	Description
<b>PM 2.5</b>	Particulate matter < 2.5um (ug/m3)
<b>PM 10</b>	Particulate matter < 10um (ug/m3)
<b>SO2</b>	Sulphur dioxide conc. (ppb)
<b>NO2</b>	Nitrogen dioxide conc. (ppb)
<b>OZONE</b>	OZONE conc. (ppb)
<b>CO</b>	Carbon monoxide conc. (ppm)
<b>AQI</b>	Air quality index
<b>updatedAt</b>	ISO timestamp of event in UTC
<b>aqiInfo</b>	Brief info about the effects of the AQI returned

## Data specifications

**Global**  
coverage

**96 hrs\***  
Forecast

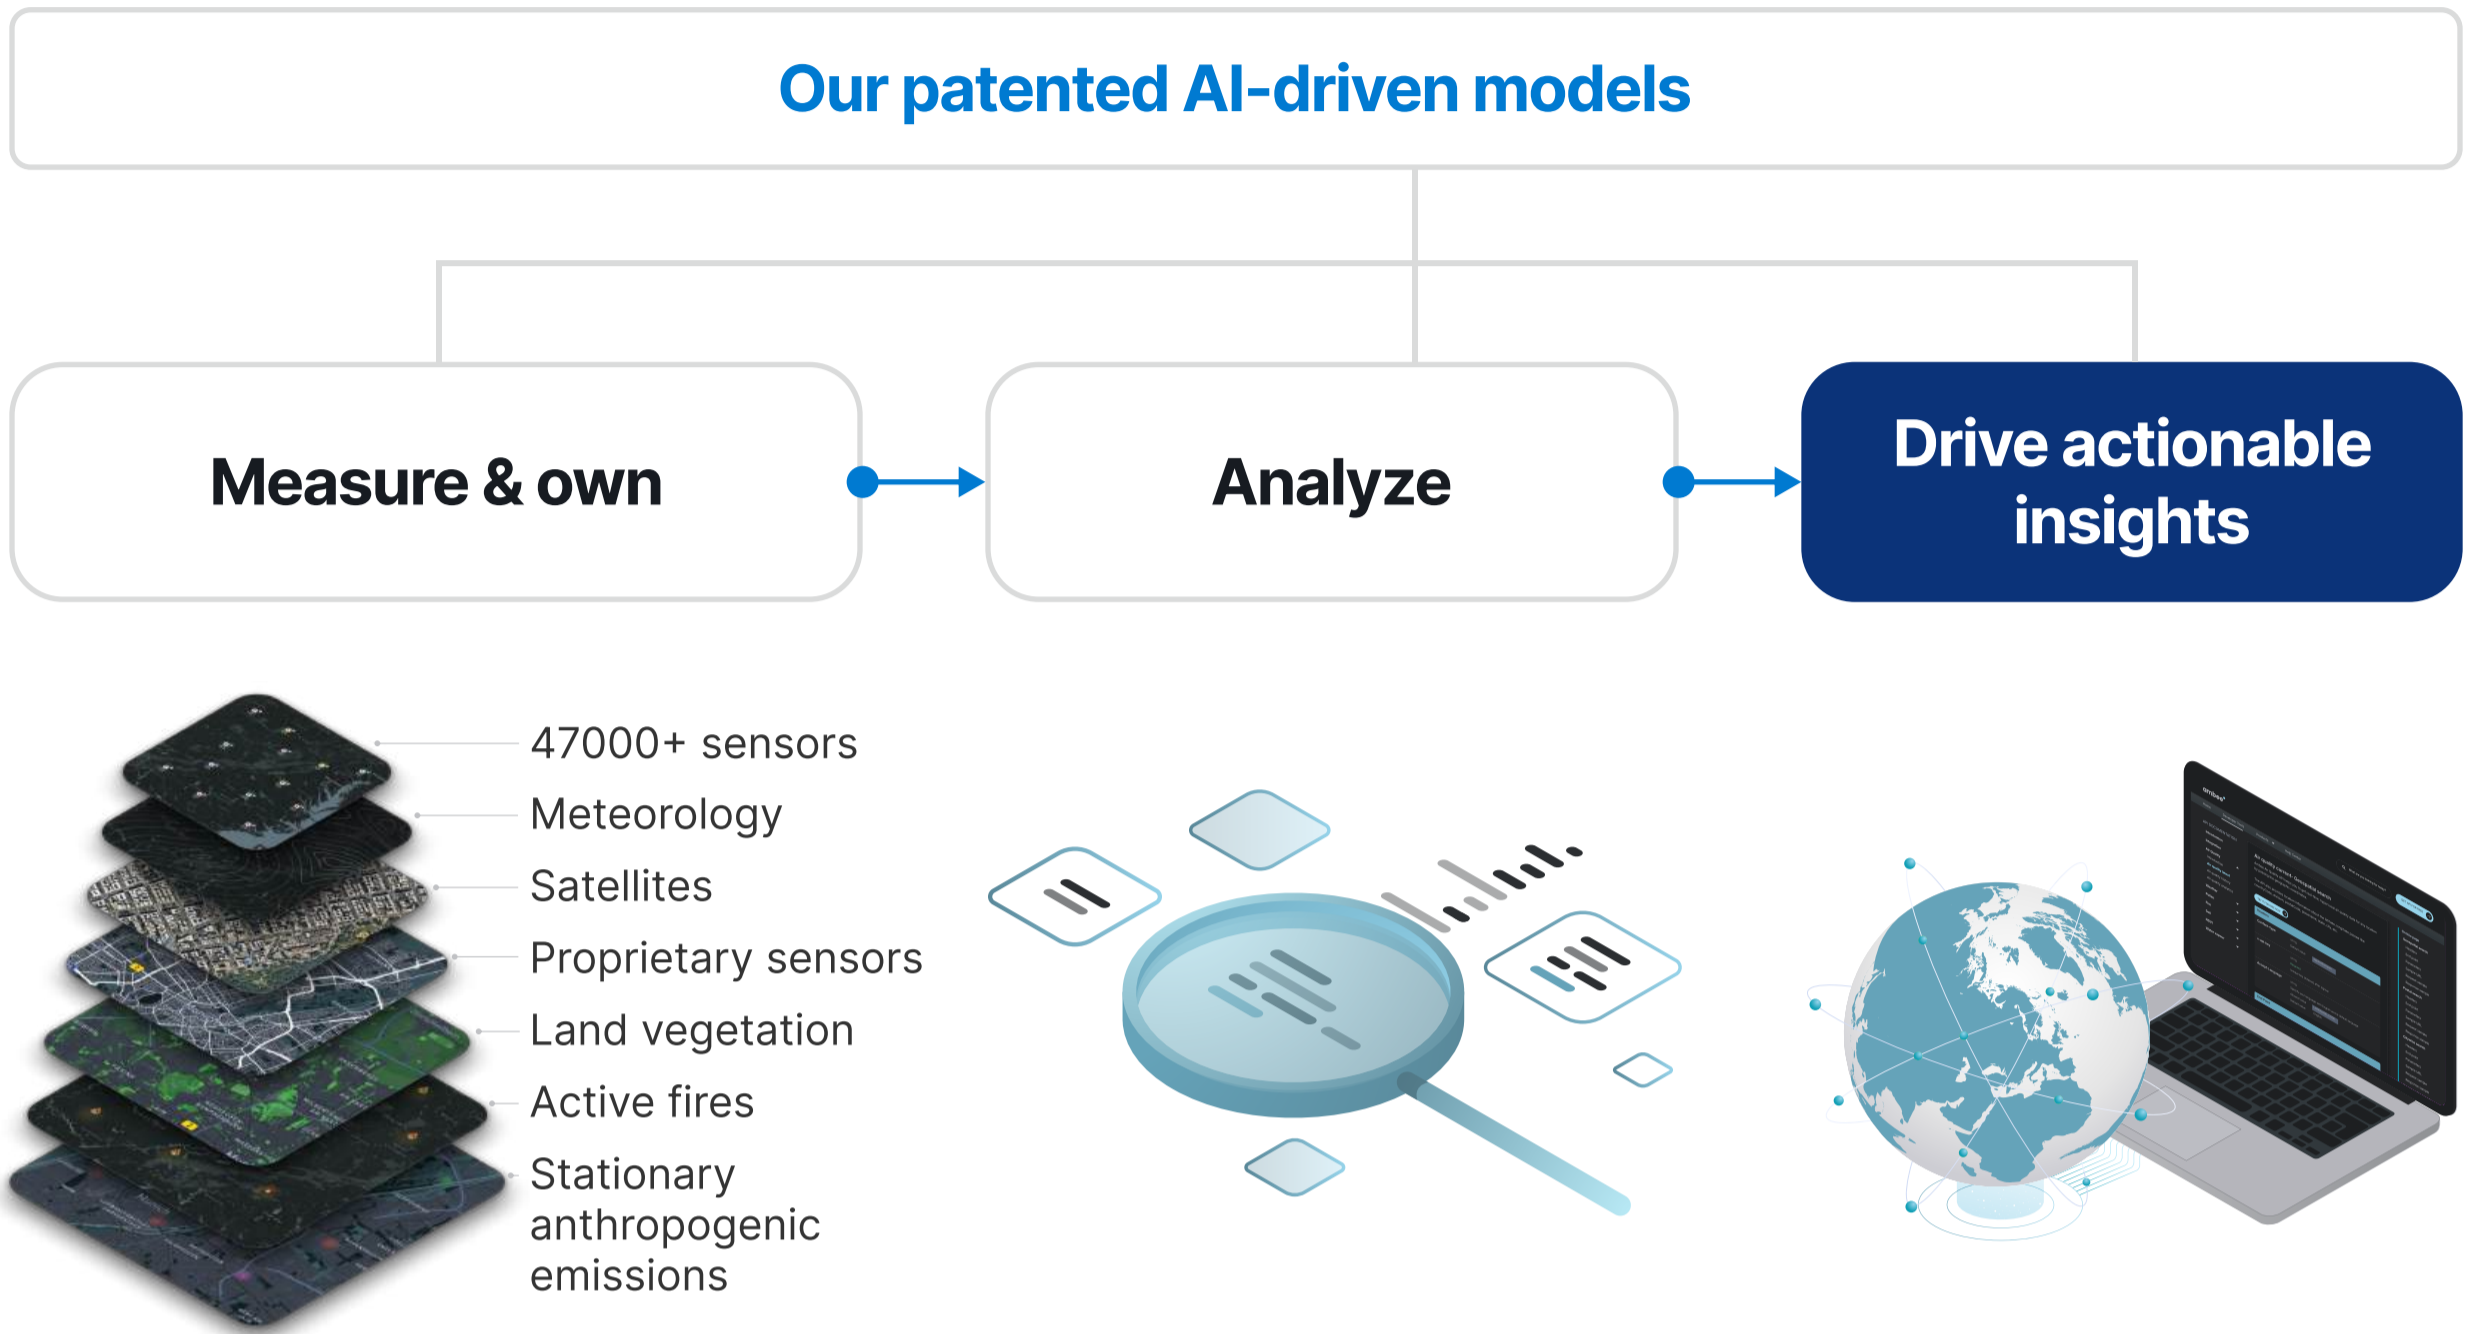

**10+ years**  
Hourly historical data

**JSON**  
Data format

**<1 sqkm**  
Granularity

\*96 hrs available on demand, 48 hrs recommended for optimal accuracy.

## Data architecture

## What makes Ambee data accurate?

- ✓ Ensures the integrity of reference-grade sensor data.
- ✓ Manages scientific anomalies/errors effectively in reference-grade sensors.
- ✓ Implements robust handling of missing values in case the station is offline.
- ✓ Deploys AI-based interpolation for precise data extrapolation within a 10km radius of the station.
- ✓ Utilizes AI-based calibration to enhance the accuracy of satellite data within a 50km proximity to the station.

- Weighted anthropogenic data
- Multiple algorithms in play throughout the ETL process
- Feature-engineered data
- Trained using 10+ years of data for each parameter
- Unique model for different geographies

# Accuracy of Ambee's real-time air quality data v/s station v/s Breezometer

## Methodology

Model application range: These models work for areas within a 10 km radius from a station.

Testing approach: We employed a 'leave one out' approach for data comparison. Consider a scenario with 5 stations, we temporarily exclude one station and utilize data from the remaining 4 stations to impute the missing station's data. Subsequently, we compare the actual data with this interpolated dataset to assess accuracy and reliability.

*Disclaimer :*

- *Since air quality is spatially correlated, interpolation gives us good results.*
- *In the graphs ahead, we see that for most stations, the air quality trends and values are captured well even if we do not know the actual value.*
- *Any lag in data is due to the station reporting the data late.*

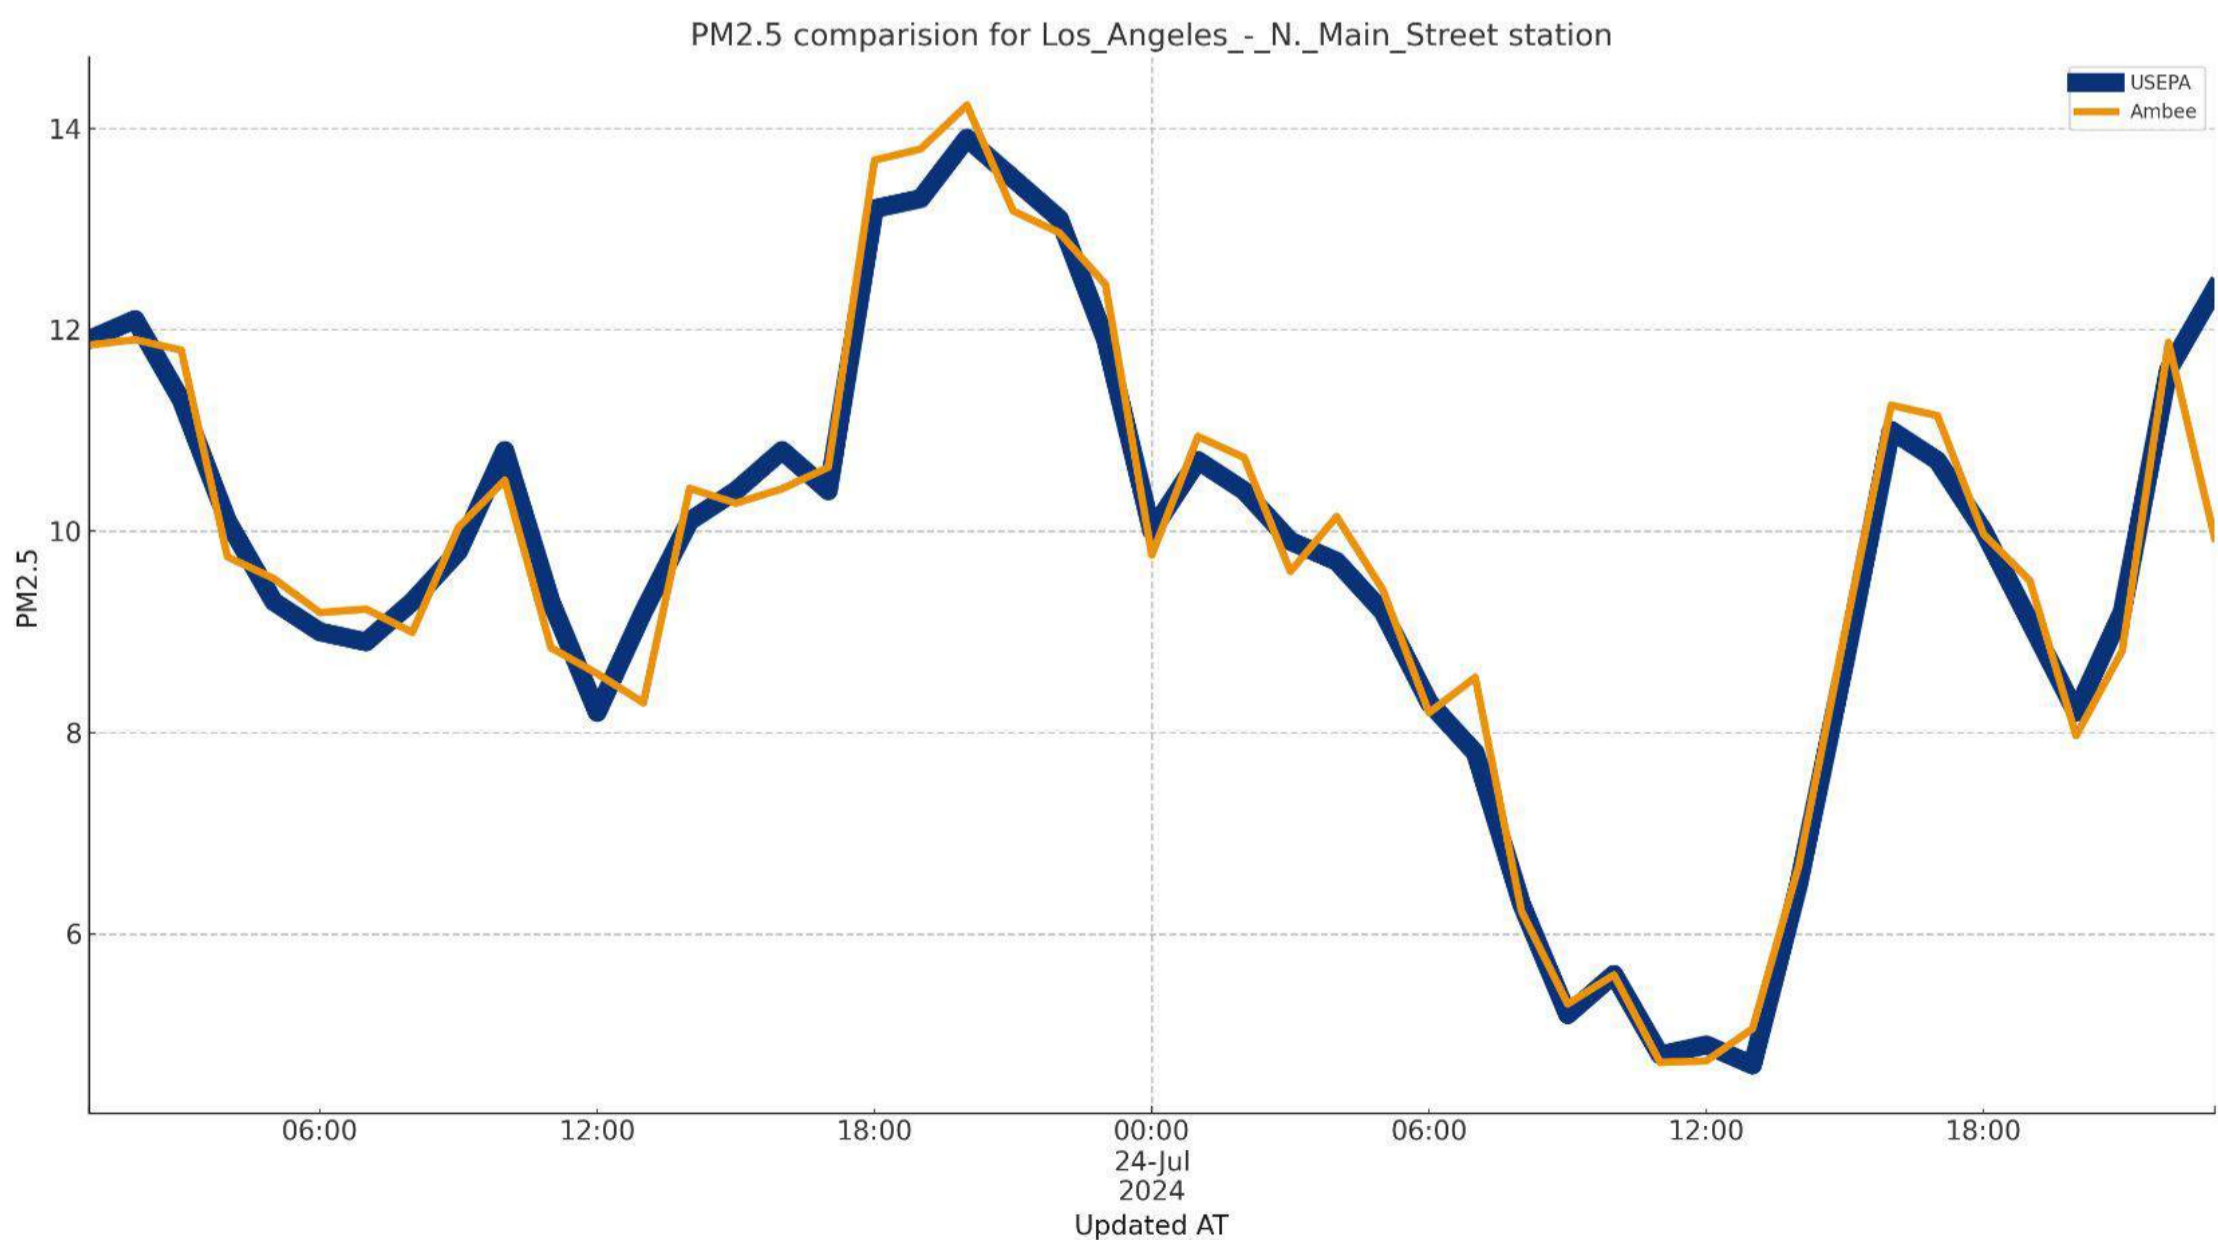

# Benchmarking ambee accuracy\* against on-ground stations: USA

\*Accuracy achieved when comparing ground station data with Ambee data for PM2.5 in the 47-48 hour timeframe.

City	Station	Ambee Accuracy*
Los Angeles	N Main Street	93%
New York	Paterson	84%
Chicago	ALSIP	83%
Houston	Bayland Park	87%
Phoenix	Tempe	81%

## Los Angeles, N Main Street

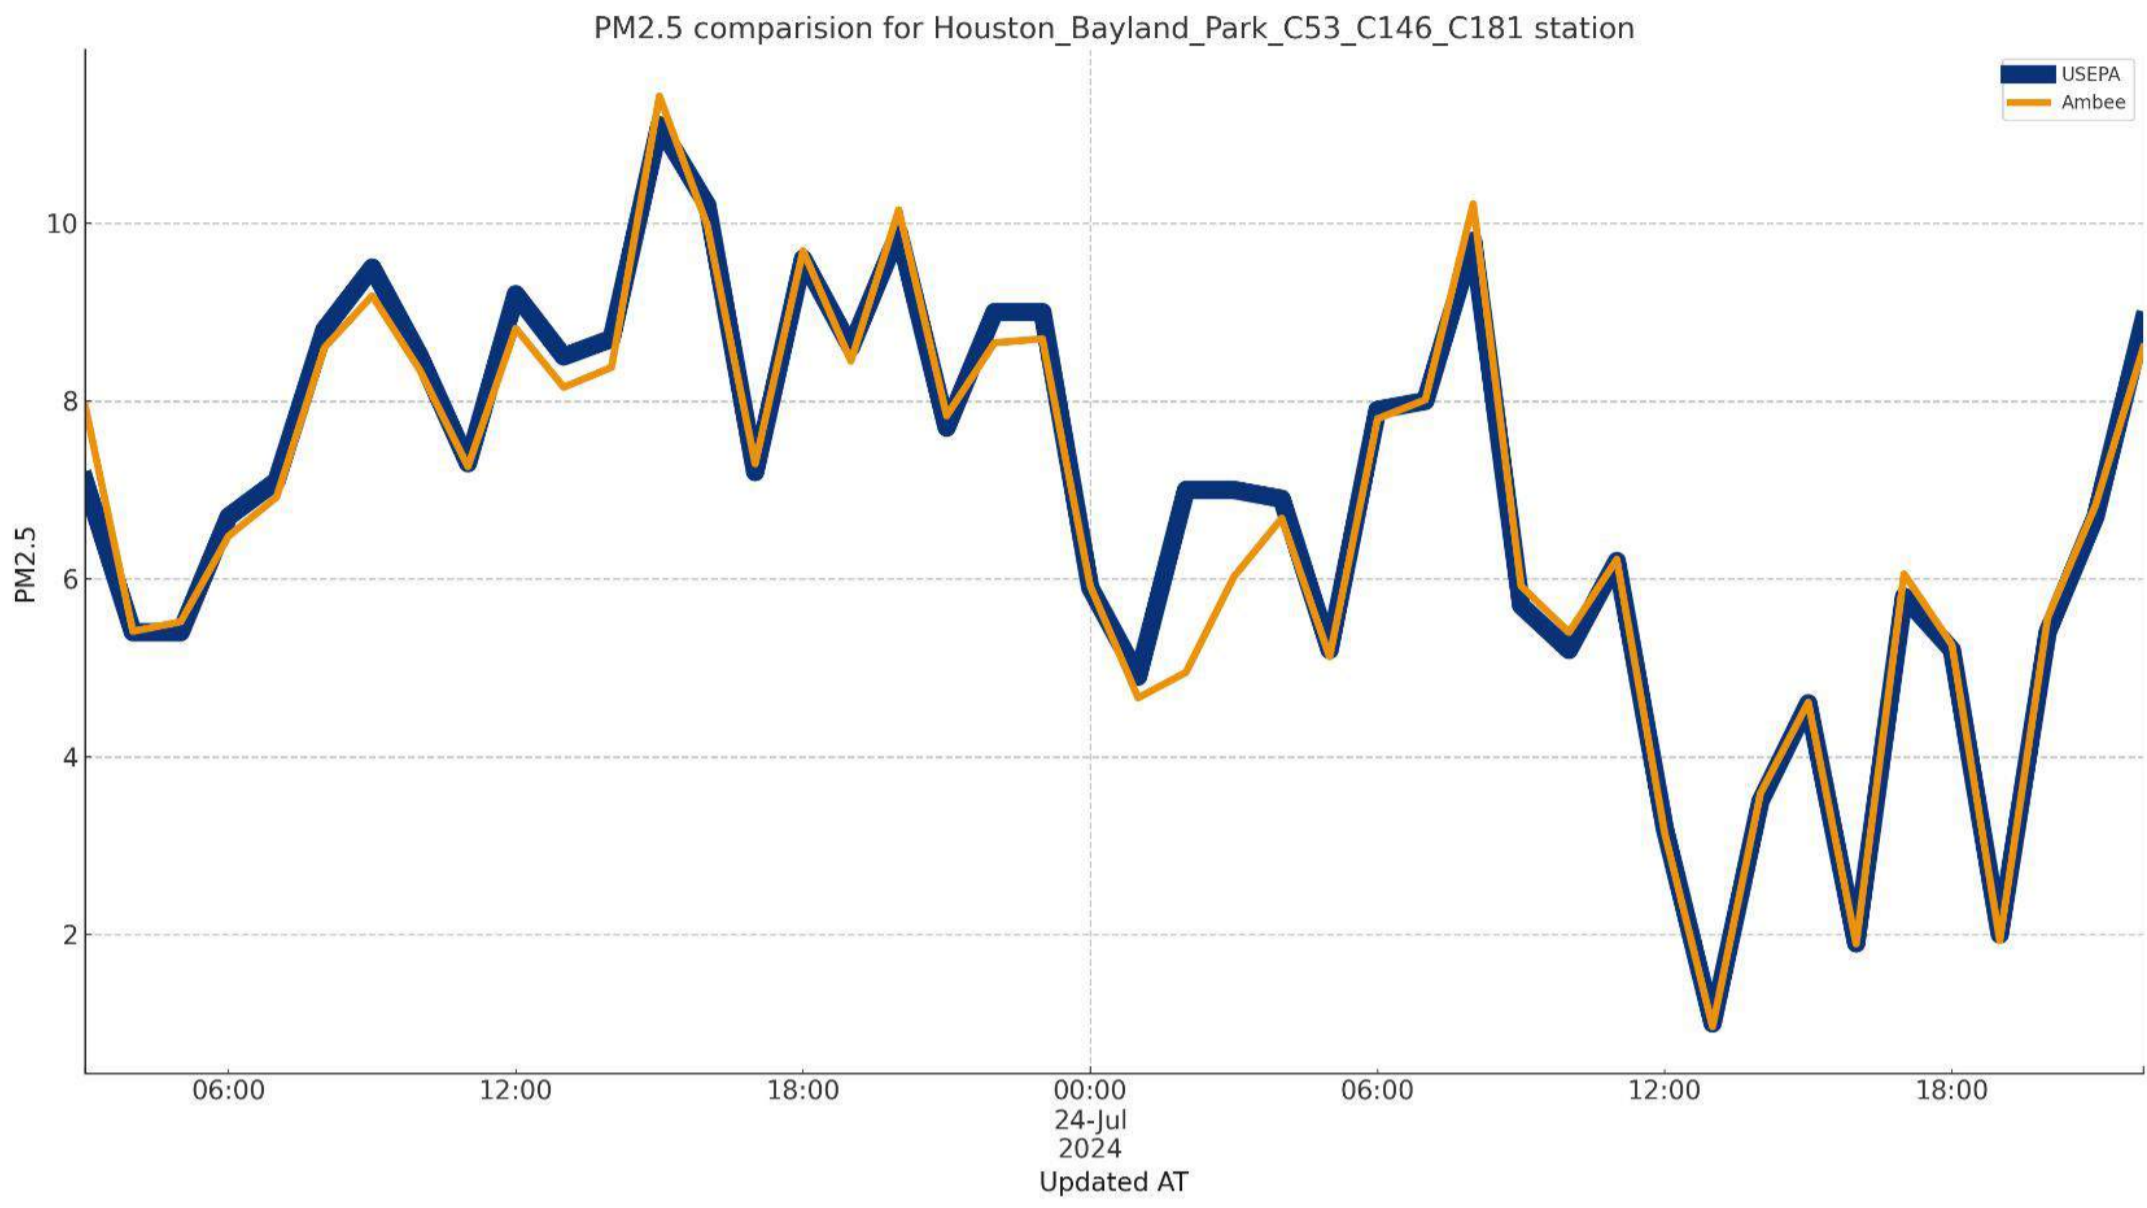

### New York, Paterson

# **Accuracy of Ambee's 48-hour air quality forecast data versus on-ground station data**

## Metrics used

**Mean absolute error:** Mean Absolute Error (MAE) is a way to measure how far off, on average, your predictions are from the actual values.

Unit - ug/m<sup>3</sup>

**Categorical accuracy:** Categorical Accuracy measures how accurately our predictions match the actual categories. Each prediction is given a score: 100% if it's an exact match, 66% if it's off by one level, 33% if it's off by two levels, and 0% if it's off by more than two levels.

Example: Actual - Good, Prediction - Good: Categorical Accuracy - 100%

Actual - Good, Prediction - Moderate: Categorical Accuracy - 66%

Unit - %

## Why these metrics?

- Mean absolute error is for people with statistical knowledge to know how close we are to actual data in terms of raw numbers.
- However, mean absolute error is hard to interpret without context. For example, MAE of 8 is extremely poor if the value ranges between 0-5 but very good if the value ranges between 100-150.
- To put things into context, we created categorical accuracy. The values are binned into categories based on USEPA Standards and this metric will check if the values are in the same range/category.
- When the average person checks the air quality, they care more about whether it's good or bad rather than the specific details, like a 3.23% error in PM<sub>2.5</sub> predictions. By combining both these metrics with visual graphs, we can provide a comprehensive and easy-to-understand overview of our forecasts.

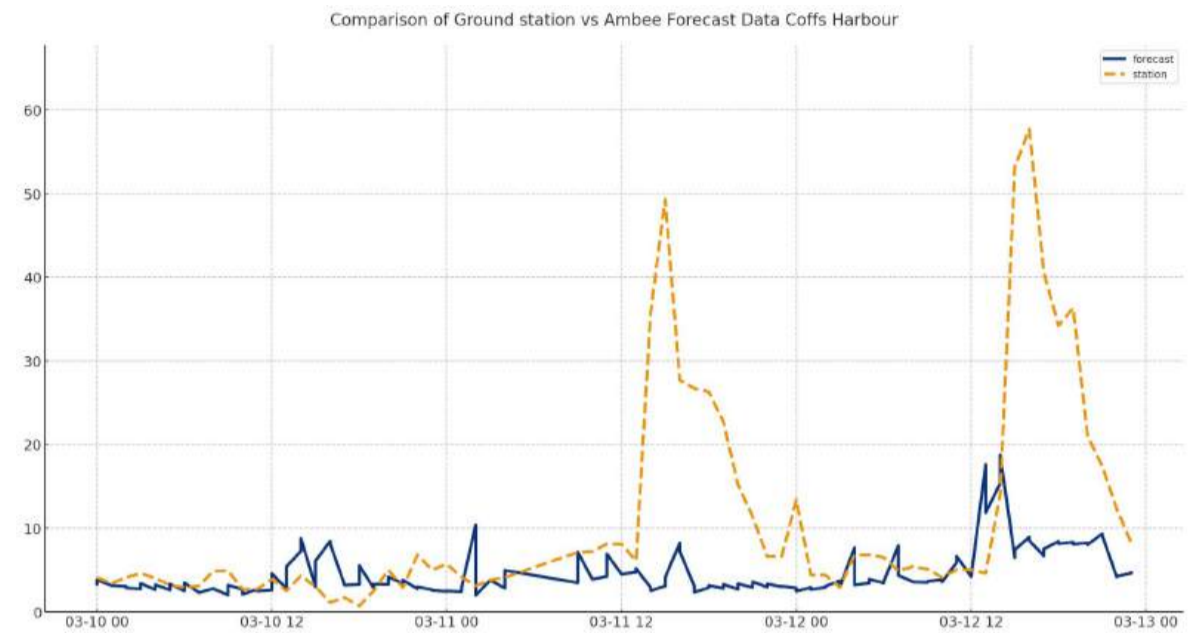

## USEPA PM<sub>2.5</sub> thresholds for binning

AQI Category	Index Values	Revised Breakpoints (ug/m <sup>3</sup> , 24-hour average)
Good	0-50	0.0-12.0
Moderate	51-100	12.1-35.4
Unhealthy for Sensitive Groups	101-150	35.5-55.4
Unhealthy	151-200	55.5-150.4
Very Unhealthy	201-300	150.5-250.4
Hazardous	301-400	250.5-350.4
	401-500	350.5-500

## Disclaimer

The accuracy is measured for a period of 48 hours. Accuracy might change for the same location later. The accuracy value should be treated as an estimate. A comparison for a period of 96 hours is possible upon request.

Air quality depends on a lot of real time factors such as human activities, fires etc hence, sudden changes in air quality cannot be predicted ahead of time. (see the image on the right for an example)

Here, the station data shows two sudden spikes that were not forecasted. Despite this, the overall categorical accuracy remains at 87%.

## Summary

Region	Average MAE	50th% MAE	Average Cat. Accuracy	50th% Cat. Accuracy
Australia	3.60	3.35	97.56	98.61
Europe	8.82	8.04	83.60	83.79
